DESIGN AND ANALYSIS OF ALGORITHMS

Unit 5: Limitations of Algorithmic Power and Coping with the Limitations

Lower-Bound Arguments

PES University

Outline

Concepts covered

- Lower-Bound Arguments
 - Trivial lower bounds
 - Adversary arguments
 - Problem reduction

1 Limitations of Algorithmic Power

- There are no algorithms to solve some problems
 - Ex: halting problem
- Other problems can be solved algorithmically, but not in polynomial time
 - Ex: traveling salesman problem
- For polynomial time algorithms also, there are lower bounds

2 Definition

Lower Bound

An estimate on a minimum amount of work needed to solve a given problem (estimate can be less than the minimum amount of work but not greater)

• Examples:

- $-\,$ number of comparisons needed to find the largest element in a set of n numbers
- number of comparisons needed to sort an array of size n
- number of comparisons necessary for searching in a sorted array
- number of multiplications needed to multiply two $n\times n$ matrices

3 Bound Tightness

- A lower bound can be:
 - an exact count
 - an efficiency class (Ω)

Tight Lower Bound

There exists an algorithm with the same efficiency as the lower bound

Problem	Lower Bound	Tightness
Sorting	$\Omega(n \log n)$	yes
Searching a sorted array	$\Omega(\log n)$	yes
Element uniqueness	$\Omega(n \log n)$	yes
Integer multiplication $(n \times n)$	$\Omega(n)$	unknown
Matrix multiplication $(n \times n)$	$\Omega(n^2)$	unknown

4 Methods for Establishing Lower Bounds

- Trivial lower bounds
- Information-theoretic arguments (decision trees)
- Adversary arguments
- Problem reduction

5 Trivial Lower Bounds

Trivial Lower Bounds

Based on counting the number of items that must be processed in input and generated as output

- Examples
 - finding max element
 - polynomial evaluation
 - sorting
 - element uniqueness
 - Hamiltonian circuit existence
- Conclusions
 - may and may not be useful
 - be careful in deciding how many elements must be processed

6 Adversary Arguments

Adversary Argument

A method of proving a lower bound by playing role of adversary that makes algorithm work the hardest by adjusting input

- Example 1: "Guessing" a number between 1 and n with yes/no questions
 - Adversary: Puts the number in a larger of the two subsets generated by last question
- Example 2: Merging two sorted lists of size n $a_1 < a_2 < \ldots < a_n$ and $b_1 < b_2 < \ldots < b_n$
 - Adversary: $a_i < b_j$ iff i < jOutput $b_1 < a_1 < b_2 < a_2 < \ldots < b_n < a_n$ requires 2n - 1 comparisons of adjacent elements

7 Problem Reduction

- Basic idea: If problem P is at least as hard as problem Q, then a lower bound for Q is also a lower bound for P
- Hence, find problem Q with a known lower bound that can be reduced to problem P in question
- Example: P is finding MST for n points in Cartesian plane Q is element uniqueness problem (known to be in $\Omega(n \log n)$)

8 Think About It

- Prove that the classic recursive algorithm for the Tower of Hanoi puzzle makes the minimum number of disk moves
- Find a trivial lower-bound class and indicate if the bound is tight:
 - finding the largest element in an array
 - generating all the subsets of an n-element set
 - determining whether \boldsymbol{n} given real numbers are all distinct
